

## Problem Set 6

### Problem 1: El Gamal encryption

As in Example 12.17 in [KL], let  $\mathbb{G}$  be the subgroup of  $\mathbb{Z}_{167}^*$  generated by  $g = 4$ . We have that the order  $q = |\mathbb{G}| = 83$  is prime. Let the secret key be  $x = 23 \in \mathbb{Z}_{83}$  and so the public key is  $pk = \langle p, q, g, h \rangle = \langle p, q, g, g^x \rangle$

- Use the square-and-multiply algorithm to compute the  $h$  component in the public key.
- Compute the encryption of message  $m = 19 \in \mathbb{G}$  with randomness  $y = 44$ .
- Decrypt the ciphertext  $\langle c_1, c_2 \rangle = \langle 132, 44 \rangle$ .
- You happen to have overheard another ciphertext  $\langle c_1, c_2 \rangle = \langle 28, 149 \rangle$ , and you know that it was encrypted with the private key corresponding to a different public key  $\langle p, q, g, h \rangle = \langle 167, 83, 4, 6 \rangle$ . What was the message?

### Problem 2: RSA

- RSA encryption** Say GenRSA outputs  $(N, e, d) = (1005973, 89, d)$ . Note that  $1005973 = 997 \cdot 1009$ .
  - Encrypt the message  $m = 1234 \in \mathbb{Z}_{1005973}^*$
  - Compute the private key  $(N, d)$  corresponding to the public key  $(N, e) = (1005973, 89)$ .
  - Decrypt the ciphertext  $c = 530339$ .
- Attacks on Plain RSA** 1. For the RSA public key  $(N, e) = (10000799791, 3)$ , decrypt the ciphertext  $c = 1000000$ . Can you do it without factoring  $N$ ?

Figure 1: Adi Shamir, Ron Rivest, and Len Adleman as MIT-students and in 2003

Image credit: <http://www.ams.org/samplings/feature-column/fcarc-internet>, <http://www.usc.edu/dept/molecular-science/RSA-2003.htm>

- Suppose we would like to use plain RSA with public exponent  $e = 3$  as public-key encryption in a hybrid scheme together with AES-256 in CBC mode. We choose  $N$  to have roughly 2048 bits. Use the previous subexercise to argue the insecurity of this hybrid scheme.

### Problem 3: CCA security of multiple encryptions

Claim 12.7 in [KL] states that if  $\Pi = (\text{Gen}, \text{Enc}, \text{Dec})$  is a CPA-secure public-key encryption scheme for fixed-length messages, then the new encryption scheme  $\Pi' = (\text{Gen}, \text{Enc}', \text{Dec}')$  with  $\text{Enc}'_{pk}(m_1 \| m_2 \| \dots \| m_\ell) = \text{Enc}_{pk}(m_1) \| \text{Enc}_{pk}(m_2) \| \dots \| \text{Enc}_{pk}(m_\ell)$  is CPA secure for arbitrary-length messages.

Show that Claim 12.7 does not hold in the setting of CCA-security: Exhibit a concrete attack on a scheme  $\Pi' = (\text{Gen}, \text{Enc}', \text{Dec}')$  constructed from a fixed-length CCA secure encryption scheme  $\Pi = (\text{Gen}, \text{Enc}, \text{Dec})$  by defining

$$\text{Enc}'_{pk}(m_1 \| m_2 \| \dots \| m_\ell) = \text{Enc}_{pk}(m_1) \| \text{Enc}_{pk}(m_2) \| \dots \| \text{Enc}_{pk}(m_\ell)$$

Make sure you specify the whole CCA attacker  $\mathcal{A}$  explicitly: what are the challenge messages, what are the encryption/decryption oracle queries, how is the guess bit  $b'$  computed? Then compute  $\Pr[\text{PubK}_{\mathcal{A}, \Pi'}^{\text{cca}}(n) = 1]!$

### Problem 4: RSA Signatures

- (a) **Plain RSA Signatures** Say the public key is  $\langle N, e \rangle = \langle 91, 11 \rangle$ .
1. Use the square-and-multiply algorithm to verify that  $(43, 36)$  is a valid message-signature pair.
  2. Compute  $\phi(N)$ .
  3. Calculate the private key  $d$ .
  4. Sign the message  $m = 28$ .
- (b) **Insecurity of plain RSA Signatures** Section 13.4.1 describes an attack on the plain RSA signature scheme in which an attacker forges a signature on an arbitrary message using two signing queries. Show how an attacker can forge a signature on an arbitrary message using a *single* signing query.
- Hint:** Use the no-query and the two-query attacks.

### Problem 5: One-time-secure signature scheme?

A signature scheme is one-time-secure if no PPT adversary making a *single* query can output a valid forgery.

Let  $f : \{0, 1\}^n \rightarrow \{0, 1\}^n$  be a one-way permutation, i.e. it is hard to calculate the inverse of  $f$ . Consider the following signature scheme for messages in the set  $\{1, \dots, n\}$ :

- To generate keys, choose uniform  $x \in \{0, 1\}^n$  and set  $y := f^{(n)}(x)$  (where  $f^{(i)}(\cdot)$  refers to  $i$ -fold iteration of  $f$ , and  $f^{(0)}(x) = x$ ). The public key is  $y$  and the private key is  $x$ .
- To sign message  $i \in \{1, \dots, n\}$ , output  $f^{(n-i)}(x)$ .
- To verify signature  $\sigma$  on message  $i$  with respect to public key  $y$ , check whether  $y = f^{(i)}(\sigma)$ .

- (a) Show that the verification procedure will output 1 for every legal message-signature pair.
- (b) Show that the above is not a one-time-secure signature scheme. Given a signature on a message  $i$ , for what messages  $j$  can an adversary output a forgery?

- (c) Prove that no PPT adversary given a signature on message  $i = 1$  can output a forgery on any message  $j > 1$  except with negligible probability.

### Problem 6: El-Gamal variant

Consider the following public-key encryption scheme. The public key is  $(G, q, g, h)$  and the private key is  $x$ , generated exactly as in the El-Gamal encryption scheme. In order to encrypt a bit  $b$ , the sender does the following:

1. If  $b = 0$  then choose independent random  $y, z \leftarrow \mathbb{Z}_q$ , compute  $c_1 = g^y$  and  $c_2 = g^z$ , and set the ciphertext equal to  $(c_1, c_2)$ .
2. If  $b = 1$  then choose a random  $y \leftarrow \mathbb{Z}_q$  and compute  $c_1 = g^y$  and  $c_2 = h^y$ . The ciphertext is  $(c_1, c_2)$ .

- (a) Show that it is possible to decrypt efficiently given knowledge of  $x$ .
- (b) Prove that this encryption scheme is EAV-secure according to Def. 12.2 if the decisional Diffie-Hellman problem is hard relative to  $\mathcal{G}$ , as defined in Def. 9.64.

### ★ Problem 7: Perfectly secure public-key encryption?

Assume a public-key encryption scheme for single-bit messages with no decryption error. Show that, given  $pk$  and a ciphertext  $c$  computed via  $c = \text{Enc}_{pk}(m)$ , it is possible for an unbounded adversary to determine  $m$  with probability 1.

### ★ Problem 8: Another one-time secure signature scheme

Let  $f$  be a permutation and  $f^{(i)}(x)$  the  $i$ -fold iteration of  $f$ , and  $f^{(0)}(x) := x$ . Let us consider the following signature scheme  $\Pi = (\text{Gen}, \text{Sign}, \text{Vrfy})$  for messages  $m \in \{1, \dots, p\}$  with  $p = p(n)$  polynomial in  $n$ .

$\text{Gen}(1^n)$  : Choose  $sk_1, sk_2 \in_R \{0, 1\}^n$ ,  $pk_1 := f^p(sk_1)$  and  $pk_2 := f^p(sk_2)$ . Set  $sk := (sk_1, sk_2)$  and  $pk := (pk_1, pk_2)$ .

$\text{Sign}_{sk}(m)$  : Compute  $\sigma_1 := f^{(p-m)}(sk_1)$  and  $\sigma_2 := f^{(m-1)}(sk_2)$ . Return  $\sigma := (\sigma_1, \sigma_2)$ .

$\text{Vrfy}_{pk}(m, \sigma)$  : If  $pk_1 = f^{(m)}(\sigma_1)$  and  $pk_2 = f^{(p-m+1)}(\sigma_2)$  return 1, else return 0.

- (a) Show that  $\Pi$  is correct.
- (b) Prove that  $\Pi$  is a one-time-secure signature scheme, if  $f$  is a one-way permutation.

★ **Problem 9: Hash-based signatures**

Read Section 14.4 in [KL] to learn about hash-based signatures, one of the prime candidates for a signature scheme which remains secure against quantum attackers.
